

Support vector machines

Hung-Hsuan Chen

Many are taken from Prof. C.-J. Lin's and J. Leskovec's slides

(Linear) support vector classification

- Data point i : $\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{id})$
- Class label of i : y_i
 - Two classes
 - Class 1: $y_i = 1$
 - Class 2: $y_i = -1$
- Find a hyperplane to separate the data points

Assume the dataset is linearly separable

- A hyperplane $\mathbf{w}^T \mathbf{x} + b = 0$
 - $\mathbf{w}^T \mathbf{x}_i + b \geq 1$ if $y_i = 1$
 - $\mathbf{w}^T \mathbf{x}_i + b \leq -1$ if $y_i = -1$
- Discriminant function $f(\mathbf{x}) = \text{sgn}(\mathbf{w}^T \mathbf{x} + b)$
 - There are **many different choices** of \mathbf{w} and b

Margin distance

- Given two parallel hyperplanes H_1 and H_2

$$H_1: \mathbf{w}^T \mathbf{x} = b_1$$

$$H_2: \mathbf{w}^T \mathbf{x} = b_2$$

- The distance between H_1 and H_2 is

$$d(H_1, H_2) = \frac{|b_1 - b_2|}{\|\mathbf{w}\|_2}$$

- Distance between $\mathbf{w}^T \mathbf{x}_i + b = 1$ and $\mathbf{w}^T \mathbf{x}_i + b = -1$:

$$\text{margin} = \frac{2}{\|\mathbf{w}\|_2}$$

Maximum margin

- $\mathbf{w}, b = \operatorname{argmax}_{\mathbf{w}, b} \frac{2}{\|\mathbf{w}\|_2}$
- This is the same as
$$\mathbf{w}, b = \operatorname{argmin}_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w}$$
- This is modeled as a **quadratic programming** problem

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w}$$

$$\text{Subject to } y_i (\mathbf{w}^T \mathbf{x}_i + b) \geq 1 \quad \forall i$$

Non-linearly separable dataset

- If non-linearly separable \rightarrow introduce penalty

$$\min_{\mathbf{w}, b} \frac{1}{2} \|\mathbf{w}\|^2 + C(\# \text{ of mistakes})$$

- If $C \rightarrow \infty$: allows no error
- If $C = 0$: basically ignores the data at all

Introduce slack variable

- Not all mistakes are equally bad

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum_{i=1}^n \xi_i$$

Subject to

$$y_i(\mathbf{w}^T \mathbf{x}_i + b) \geq 1 - \xi_i \quad \forall i$$

- If a point is on the wrong side \rightarrow get penalty ξ_i

For each data point \mathbf{x} :

If $d(\mathbf{x}, L) \geq 1$ and at the right side:
don't care

Else: pay linear penalty

Soft margin classification

- Why soft margin
 - The training data may not be linearly separable
 - Even if the training data is linearly separable, allowing some error may increase the margin
- Essentially, there are two objectives (which may be against each other)
 - Minimize the training error
 - Prevent error
 - Maximize the margin
 - Prevent overfitting (allow some error)

Soft margin classification formula

- Original (linear) formula

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w}$$

Subject to

$$y_i(\mathbf{w}^T \mathbf{x}_i + b) \geq 1 \quad \forall i$$

- New formula

$$\min_{\mathbf{w}, b} \left(\frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum_i \xi_i \right)$$

Subject to

$$y_i(\mathbf{w}^T \mathbf{x}_i + b) \geq 1 - \xi_i$$

and $\xi_i > 0 \quad \forall i$

- C: control overfitting
 - A large C makes most ξ_i 's to zero
- ξ_i : slack variables

Linear SVM with soft margin

- Linear SVM

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum_{i=1}^n \xi_i$$

Subject to

$$y_i(\mathbf{w}^T \mathbf{x}_i + b) \geq 1 - \xi_i \quad \forall i$$

- This is the same as

$$\min_{\mathbf{w}, b} \left(\underbrace{\frac{1}{2} \mathbf{w}^T \mathbf{w}}_{\text{Margin inverse}} + \underbrace{C \sum_{i=1}^n \max \left\{ 0, 1 - y_i(\mathbf{w}^T \mathbf{x}_i + b) \right\}}_{\text{Empirical loss } L \text{ (how well we fit training data)}} \right)$$

↑
↑
↑

Margin inverse

Regularization
parameter

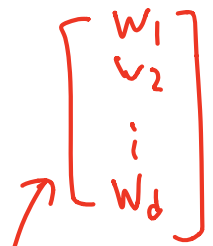

Empirical **loss** L (how well we fit
training data)

~~if data incorrect predicted~~
 $1 - 0$ would be positive
 would be $1 - 0 (> 0)$

~~if data correct predicted~~
 $1 - 0$ would be negative
 would be 0
 If the point is at the wrong
 side, get loss proportional to ξ_i

Derivatives

↓
結合後可用 GD

$$f(\mathbf{w}, b) = \frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum_{i=1}^n \max \left\{ 0, 1 - y_i (\mathbf{w}^T \mathbf{x}_i + b) \right\}$$

$$\Rightarrow \nabla_{w_j} f = w_j + C \sum_{i=1}^n \frac{\partial \max \left\{ 0, 1 - y_i (\mathbf{w}^T \mathbf{x}_i + b) \right\}}{\partial w_j} = \begin{cases} w_j & \text{if } y_i (\mathbf{w}^T \mathbf{x}_i + b) \geq 1 \\ w_j + C(-y_i x_{ij}) & \text{else} \end{cases}$$

means correct predicted

cause: $1 - y_i (\mathbf{w}^T \mathbf{x}_i + b) < 0$

Solve Linear SVM by GD

```
While (true) {  
    for (j=1,2, ..., d) {
```

~~Note: b is batch size~~

$$\nabla_{w_j} f(\mathbf{x}_{1:\cancel{N}}) = w_j + C \sum_{i=1}^{\cancel{N}} \frac{\partial \max \left\{ 0, 1 - y_i (\mathbf{w}^T \mathbf{x}_i + b) \right\}}{\partial w_j}$$

$$w_j = w_j - \alpha \nabla_{w_j} f$$

```
}
```

```
if ( $\mathbf{w}$  converges) break
```

```
}
```

Solve Linear SVM by SGD

```
for (i=1,2, ..., n){  
  for (j=1,2, ..., d){  
    
$$\nabla_{w_j} f(\mathbf{x}_i) = w_j + C \frac{\partial \max \left\{ 0, 1 - y_i (\mathbf{w}^T \mathbf{x}_i + b) \right\}}{\partial w_j}$$
  
    
$$w_j = w_j - \alpha \nabla_{w_j} f$$
  
  }  
  
  if ( $\mathbf{w}$  converges) break  
}
```

- Detour

- Lagrange multiplier
- KKT condition

use to check Lagrange 是否满足
solution!

- Math caution!

- If you get lost, I hope you at least understand the linear SVM

Generalized Lagrange multiplier

- Standard form problem

Minimize $f(\mathbf{x})$ subject to $g_i(\mathbf{x}) \leq 0$ ($i = 1, \dots, p$)
and $h_j(\mathbf{x}) = 0$ ($j = 1, \dots, m$)

- Lagrangian

$$\mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu}) = f(\mathbf{x}) + \sum_{i=1}^p \lambda_i g_i(\mathbf{x}) + \sum_{j=1}^m \mu_j h_j(\mathbf{x})$$

The characteristic of the solution

SVM (ignore slack variables):

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w}$$

Subject to

$$y_i(\mathbf{w}^T \mathbf{x}_i + b) \geq 1 \quad \forall i$$

$$\mathcal{L}(\mathbf{w}, b, \lambda) = \frac{1}{2} \mathbf{w}^T \mathbf{w} + \sum \lambda_i [1 - y_i(\mathbf{w}^T \mathbf{x}_i + b)]$$

– No equality constraints (no μ 's)

- Based on the KKT condition: if \mathbf{w}^* is the optimal solution to the standard form problem, then there exist KKT multipliers λ and μ such that

- Lagrangian optimality

$$\nabla \mathcal{L}(\mathbf{w}^*, \lambda, \mu) = 0 \quad (1)$$

- Primal feasibility

$$g_i(\mathbf{w}^*) \leq 0 \quad \forall i \quad (2)$$

$$h_j(\mathbf{w}^*) = 0 \quad \forall j \quad (3)$$

- **Dual feasibility**

$$\lambda_i \geq 0 \quad \forall i \quad (4)$$

- **Complementary slackness**

$$\lambda_i g_i(\mathbf{w}^*) = 0 \quad \forall i \quad (5)$$

- Assume linearly-separable, by condition (4) and (5):

- If a training instance \mathbf{x}_i is **not** on the **two hyperplanes** (i.e., $g_i(\mathbf{w}^*) < 0$), λ_i must be 0

- If a training instance \mathbf{x}_i is on the two hyperplanes (i.e., $g_i(\mathbf{w}^*) = 0$), $\lambda_i \geq 0$

$$w^T x + b = -1$$

$$w^T x + b = 1$$

$$\oplus w^T x + b \geq 1$$

$$w^T \mathbf{x}_i + b = 1 \text{ and } w^T \mathbf{x}_i + b = -1$$

只有线上的 $g(\mathbf{w}^*) = 0$

以外的 $\lambda = 0$, 而

$g()$ 和

Map features to higher dimensional

- Transform the data into a higher dimension feature space so that linear separation is possible
 - Higher dimensional (**could be infinite**) feature space

$$\bullet \underbrace{\phi(\mathbf{x}_i)}_{\downarrow} = \left[\phi_1(\mathbf{x}_i), \phi_2(\mathbf{x}_i), \dots \right]^T$$

2D to 3D

Example

- The positive and negative examples are not linearly-separable by the 2D features (x_1, x_2)

• If we add one more feature

$x_3 = x_1^2 + x_2^2$, the blue points are those with $x_3 \leq 0.6^2$, and the red points are those with $x_3 > 0.6^2$

– $\phi(x_1, x_2) = (x_1, x_2, x_3) = (x_1, x_2, x_1^2 + x_2^2)$

• 2D to 3D

- The points become linearly separable

Kernel SVM

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w}$$

$$\text{Subject to } y_i (\mathbf{w}^T \phi(\mathbf{x}_i) + b) \geq 1$$

Here we ignore the slack variables for simplicity

- Linear SVM: length of \mathbf{w} is d (the same as the size of \mathbf{x}_i)
- Kernel SVM: length of \mathbf{w} is larger than d (the same as the size of $\phi(\mathbf{x}_i)$)
 - Kernel SVM can fit a more complex function
 - The size of $\phi(\mathbf{x}_i)$ is large (and could be *infinity*)
 - How to efficiently compute \mathbf{w} and $\mathbf{w}^T \phi(\mathbf{x}_i)$?
 - How to store \mathbf{w} ?

Lagrangian of kernel SVM

$$\mathcal{L}(\mathbf{w}, b, \lambda) = \frac{1}{2} \mathbf{w}^T \mathbf{w} + \sum \lambda_i \left[1 - y_i (\mathbf{w}^T \phi(\mathbf{x}_i) + b) \right]$$

$$\begin{cases} \nabla_{\mathbf{w}} \mathcal{L}(\mathbf{w}, b, \lambda) = \mathbf{w} - \sum \lambda_i y_i \phi(\mathbf{x}_i) := 0 \end{cases}$$

$$\begin{cases} \nabla_b \mathcal{L}(\mathbf{w}, b, \lambda) = - \sum \lambda_i y_i := 0 \end{cases}$$

$$\Rightarrow \begin{cases} \mathbf{w} = \sum \lambda_i y_i \phi(\mathbf{x}_i) \\ \sum \lambda_i y_i := 0 \end{cases}$$

- Given a test instance \mathbf{x}_t , the discriminant function is

$$f(\mathbf{x}_t) = \mathbf{w}^T \phi(\mathbf{x}_t) + b = \sum \lambda_i y_i \underbrace{\phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t)} + b$$

- Prediction is a **linear combination of training instances** $\mathbf{w}^T \phi(\mathbf{x}_t)$ plus bias

High dimensional mapping example

$$f(\mathbf{x}_t) = \mathbf{w}^T \phi(\mathbf{x}_t) + b = \sum \lambda_i y_i \phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t) + b$$

- Example:

- $\mathbf{x}_i = [x_{i1}, x_{i2}]^T \in R^2, \phi(\mathbf{x}_i) \in R^6$

- If we set (*assume*)

$$\phi(\mathbf{x}_i) = [1, \sqrt{2}x_{i1}, \sqrt{2}x_{i2}, \sqrt{2}x_{i1}x_{i2}, x_{i1}^2, x_{i2}^2]^T$$

- Then

$$\phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t) = 1 + x_{i1}^2 x_{t1}^2 + x_{i2}^2 x_{t2}^2 + 2x_{i1}x_{t1} + 2x_{i2}x_{t2} + 2x_{i1}x_{t1}x_{i2}x_{t2}$$

- When the target dimension is large, it is inefficient to generate $\phi(\mathbf{x}_t)$ and $\phi(\mathbf{x}_i) \forall i$ and perform the dot product

Kernel trick example

- If

$$\phi(\mathbf{x}_i) = [1, \sqrt{2}x_{i1}, \sqrt{2}x_{i2}, \sqrt{2}x_{i1}x_{i2}, x_{i1}^2, x_{i2}^2]^T,$$

then:

- $\phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t) = (1 + \mathbf{x}_i^T \mathbf{x}_t)^2$

- Computing $(1 + \mathbf{x}_i^T \mathbf{x}_t)^2$ is much more efficient than computing $\phi(\mathbf{x}_i)$, $\phi(\mathbf{x}_t)$, and then $\phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t)$

Kernel trick example

$$f(\mathbf{x}_t) = \mathbf{w}^T \phi(\mathbf{x}_t) + b = \sum \lambda_i y_i \boxed{\phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t)} + b$$

所以計算

- If $\phi(\mathbf{x}_i)$'s dimension is very high

- Store \mathbf{w} is costly

- Compute discriminant function $f(\mathbf{x}_t) = \mathbf{w}^T \phi(\mathbf{x}_t) + b$ is costly

- We may use $(1 + \mathbf{x}_i^T \mathbf{x}_T)^2$ to efficiently map features to higher dimension

- We compute

$$\sum \lambda_i y_i \phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t) + b = \sum \lambda_i y_i (1 + \mathbf{x}_i^T \mathbf{x}_T)^2 + b \text{ as the discriminant function}$$

most of data are 0
只有在線性的才 > 0

Popular kernels

- Linear kernel (i.e., linear SVM)

$$K(\mathbf{x}_i, \mathbf{x}_t) = \mathbf{x}_i^T \mathbf{x}_t = \langle \mathbf{x}_i, \mathbf{x}_t \rangle$$

- Polynomial kernel

$$K(\mathbf{x}_i, \mathbf{x}_t) = \left(\langle \mathbf{x}_i, \mathbf{x}_t \rangle + r \right)^d, \quad r > 0$$

- Gaussian (RBF) kernel

$$K(\mathbf{x}_i, \mathbf{x}_t) = \exp\left(-\gamma \|\mathbf{x}_i - \mathbf{x}_t\|^2\right)$$

- The dimension of $K(\mathbf{x}_i, \mathbf{x}_t)$ could be **infinity** (e.g., RBF kernel), but the dimensions of \mathbf{x}_i and \mathbf{x}_t are finite

Mapping to infinite dimensional

By Taylor expansion:

$$e^x = \sum_{i=0}^{\infty} \frac{x^i}{i!}$$

- Assume $\mathbf{x}_i \in R^1$, $\gamma > 0$

$$\begin{aligned} \exp\left(-\gamma\|\mathbf{x}_i - \mathbf{x}_t\|^2\right) &= \exp\left(-\gamma(\mathbf{x}_i - \mathbf{x}_t)^2\right) = \exp\left(-\gamma\mathbf{x}_i^2 + 2\gamma\mathbf{x}_i\mathbf{x}_t - \gamma\mathbf{x}_t^2\right) \\ &= \exp\left(-\gamma\mathbf{x}_i^2 - \gamma\mathbf{x}_j^2\right) \cdot \exp\left(2\gamma\mathbf{x}_i\mathbf{x}_j\right) \\ &= \exp\left(-\gamma\mathbf{x}_i^2 - \gamma\mathbf{x}_j^2\right) \left(1 + \frac{2\gamma\mathbf{x}_i\mathbf{x}_j}{1!} + \frac{(2\gamma\mathbf{x}_i\mathbf{x}_j)^2}{2!} + \frac{(2\gamma\mathbf{x}_i\mathbf{x}_j)^3}{3!} + \dots\right) \\ &= \exp\left(-\gamma\mathbf{x}_i^2 - \gamma\mathbf{x}_j^2\right) \left(1 \cdot 1 + \sqrt{\frac{2\gamma}{1!}}\mathbf{x}_i\sqrt{\frac{2\gamma}{1!}}\mathbf{x}_j + \sqrt{\frac{(2\gamma)^2}{2!}}\mathbf{x}_i^2\sqrt{\frac{(2\gamma)^2}{2!}}\mathbf{x}_j^2 + \sqrt{\frac{(2\gamma)^3}{3!}}\mathbf{x}_i^3\sqrt{\frac{(2\gamma)^3}{3!}}\mathbf{x}_j^3 + \dots\right) \\ &= \phi(\mathbf{x}_i)^T \phi(\mathbf{x}_j), \end{aligned}$$

$$\text{Where } \phi(\mathbf{x}_i) = \exp(-\gamma\mathbf{x}_i^2) \left[1, \sqrt{\frac{2\gamma}{1!}}\mathbf{x}_i, \sqrt{\frac{(2\gamma)^2}{2!}}\mathbf{x}_i^2, \sqrt{\frac{(2\gamma)^3}{3!}}\mathbf{x}_i^3, \dots \right]^T$$

Characteristics of the solution

- Discriminant function
$$f(\mathbf{x}_t) = \mathbf{w}^T \phi(\mathbf{x}_t) + b = \sum \lambda_i y_i \underbrace{K(\mathbf{x}_i, \mathbf{x}_t)}_{\phi(\mathbf{x}_i)^T \phi(\mathbf{x}_t)} + b$$
- Many λ_i 's are 0
 - Memorizing training instance (\mathbf{x}_i, y_i) only if $\lambda_i > 0$
 - We don't need to form \mathbf{w} explicitly
- To predict the label of a test instance \mathbf{x}_t , we need to compute the Kernel of the test instance with the training instances **whose λ_i 's are larger than zeros**
 - These training instances are called “support vectors”

Visualizing “support vectors”

11/3

A numerical example

- Training data: five 1D data points with labels

- First class (+1): $x_{1,1} = 1$, $x_{2,1} = 2$, $x_{5,1} = 6$

- Second class (-1): $x_{3,1} = 4$, $x_{4,1} = 5$

- Non-linearly separable
- Use polynomial kernel with degree 2

$$K(\mathbf{x}_i, \mathbf{x}_t) = \left(\langle \mathbf{x}_i, \mathbf{x}_t \rangle + 1 \right)^2$$

- Solve λ_i ($i = 1, \dots, 5$) by a standard QP solver

- $[\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5] = [0, 2.5, 0, 7.333, 4.833]$

The discriminant function of the example

- $[\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5] = [0, 2.5, 0, 7.333, 4.833]$
 - Since $\lambda_1 = \lambda_3 = 0$, the support vectors are $(x_2, x_4, x_5) = (2, 5, 6)$
- The discriminant function
 - $f(z) = \sum \lambda_i y_i \phi(x_i)^T \phi(z) + b$
$$= \left[2.5(1)(2z + 1)^2 + 7.333(-1)(5z + 1)^2 + 4.833(1)(6z + 1)^2 \right] + b$$
$$= 0.6667z^2 - 5.333z + b$$
 - Since $f(x_{2,1}) = f(x_{5,1}) = 1$ and $f(x_{4,1}) = -1$, we can get $b=9$
 - $f(z) = 0.6667z^2 - 5.333z + 9$

Visualize the discriminant function

Standard SVM

- Standard form

$$\min_{\mathbf{w}, b} \frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum_i \xi_i$$

Subject to (1) $y_i (\mathbf{w}^T \phi(\mathbf{x}_i) + b) \geq 1 - \xi_i$

(2) $\xi_i > 0 \quad \forall i$

Review of SVM

- Large margin
 - Prevent overfitting
- Soft margin
 - Make the margin become larger
 - Prevent overfitting
- Kernel trick
 - Make the data linearly separable
 - Efficiently transform the input features into high (could be infinite) dimensional space

Revisiting logistic regression and SVM from another viewpoint

Deriving SVM and LogReg from regularized linear classification

- We derived SVM from the viewpoint of maximal margin
- We derived logistic regression from maximizing the log-likelihood (or minimizing the cross entropy loss)
- However, both can be considered from the viewpoint of **regularized linear classification**

Regularized linear classification

- Training data:

$$\{\mathbf{x}_i, y_i\}_{i=1, \dots, n}, \mathbf{x}_i \in R^d, y_i \in \{\pm 1\}$$

- Objective

$$\min_{\mathbf{w}} f(\mathbf{w}), f(\mathbf{w}) \equiv \frac{\mathbf{w}^T \mathbf{w}}{2} + C \sum_{i=1}^n \xi(\mathbf{w}; \mathbf{x}_i, y_i)$$

– $\xi(\mathbf{w}; \mathbf{x}_i, y_i)$: loss function; we hope $y_i \mathbf{w}^T \mathbf{x} > 0$

- Trying to fit the training data

– $(\mathbf{w}^T \mathbf{w})/2$: regularization term

- We skip the L1 regularization term here
- Prevent over-fit the training data

– C : regularization parameter

Loss functions

- Common loss functions in classification
 - Hinge loss
 - $\xi_{L1}(\mathbf{w}; \mathbf{x}_i, y_i) = \max(0, 1 - y_i \mathbf{w}^T \mathbf{x}_i)$
 - Squared hinge loss
 - $\xi_{L2}(\mathbf{w}; \mathbf{x}_i, y_i) = \max(0, 1 - y_i \mathbf{w}^T \mathbf{x}_i)^2$
 - Logistic loss
 - $\xi_{LR}(\mathbf{w}; \mathbf{x}_i, y_i) = \log(1 + e^{-y_i \mathbf{w}^T \mathbf{x}_i})$
 - This is different from what we derived previously
 - » We used 1/0 to encode two classes before, but here we use +1/-1
- SVM: ξ_{L1} and ξ_{L2}
- Logistic Regression: ξ_{LR}

Visualizing the loss functions

Regularized linear classification **with kernel**

- Training data:

$$\{\mathbf{x}_i, y_i\}_{i=1, \dots, m}, \mathbf{x}_i \in R^n, y_i \in \{\pm 1\}$$

- Objective

$$\min_{\mathbf{w}} f(\mathbf{w}), f(\mathbf{w}) \equiv \frac{\mathbf{w}^T \mathbf{w}}{2} + C \sum_{i=1}^m \xi(\mathbf{w}; \phi(\mathbf{x}_i), y_i)$$

– $\xi(\mathbf{w}; \phi(\mathbf{x}_i), y_i)$: loss function; we hope $y_i \mathbf{w}^T \phi(\mathbf{x}_i) > 0$

- Trying to fit the training data

– $\mathbf{w}^T \mathbf{w}/2$: regularization term

- We skip the L1 regularization term here
- Prevent over-fit the training data

– C : regularization parameter

Logistic regression vs SVM

- Logistic regression and SVM are very related
- Their performance (i.e., test accuracy) is usually similar
- Due to the naming, the typical deriving process, and historical reasons, many believe that SVM and logistic regression are very different
 - This is a misunderstanding

Linear or kernel? SVM or Logistic Regression?

- When people say SVM, they typically mean “**kernel** SVM”
 - But there is **linear** SVM

$$\min_{\mathbf{w}} f(\mathbf{w}), f(\mathbf{w}) \equiv \frac{\mathbf{w}^T \mathbf{w}}{2} + C \sum_{i=1}^m \max(0, 1 - y_i \mathbf{w}^T \mathbf{x}_i)$$

- When people say logistic regression, they typically mean “**linear** logistic regression”
 - But there is **kernel** logistic regression

$$\min_{\mathbf{w}} f(\mathbf{w}), f(\mathbf{w}) \equiv \frac{\mathbf{w}^T \mathbf{w}}{2} + C \sum_{i=1}^m \log(1 + e^{-y_i \mathbf{w}^T \phi(\mathbf{x}_i)})$$

- However, kernel logistic regression is rarely used in practice
 - Most λ_i are not zero \rightarrow if we want to apply the kernel trick (instead of storing \mathbf{w} explicitly), almost all training samples need to be memorized

Regularized linear regression

- Training data:

$$\{\mathbf{x}_i, y_i\}_{i=1, \dots, m}, \mathbf{x}_i \in R^n, y_i \in R^1$$

- Objective

$$\min_{\mathbf{w}} \left(\frac{\mathbf{w}^T \mathbf{w}}{2} + C \sum_{i=1}^m \xi(\mathbf{w}; \mathbf{x}_i, y_i) \right)$$

- $\xi(\mathbf{w}; \mathbf{x}_i, y_i)$: loss function
 - Trying to fit the training data
- $\mathbf{w}^T \mathbf{w}/2$: regularization term
 - We skip the L1 regularization term here
 - Prevent over-fit the training data
- C : regularization parameter

Loss functions for regression

- Some commonly used loss functions

- L1 loss

- $\xi_{L1}(\mathbf{w}; \mathbf{x}_i, y_i) = |y_i - \mathbf{w}^T \mathbf{x}_i|$

- L2 loss

- $\xi_{L2}(\mathbf{w}; \mathbf{x}_i, y_i) = (y_i - \mathbf{w}^T \mathbf{x}_i)^2$

- ϵ -insensitive loss

- $\xi_{\epsilon}(\mathbf{w}; \mathbf{x}_i, y_i) = \max(|\mathbf{w}^T \mathbf{x}_i - y_i| - \epsilon, 0)$

- ϵ -insensitive square loss

- $\xi_{\epsilon 2}(\mathbf{w}; \mathbf{x}_i, y_i) = \max(|\mathbf{w}^T \mathbf{x}_i - y_i| - \epsilon, 0)^2$

- SVM (support vector regression): $\xi_{\epsilon}, \xi_{\epsilon 2}$

- Linear Regression: ξ_{L2}

Regularized regression with kernel

- Training data:

$$\{\mathbf{x}_i, y_i\}_{i=1, \dots, m}, \mathbf{x}_i \in R^n, y_i \in R^1$$

- Objective

$$\min_{\mathbf{w}} f(\mathbf{w}), f(\mathbf{w}) \equiv \frac{\mathbf{w}^T \mathbf{w}}{2} + C \sum_{i=1}^m \xi(\mathbf{w}; \phi(\mathbf{x}_i), y_i)$$

- $\xi(\mathbf{w}; \phi(\mathbf{x}_i), y_i)$: loss function
 - Trying to fit the training data
- $\mathbf{w}^T \mathbf{w}/2$: regularization term
 - We skip the L1 regularization term here
 - Prevent over-fit the training data
- C : regularization parameter

Summary

- The same classification method can be derived from different ways
 - SVM
 - Maximize margin
 - Minimizing training loss with regularization constraints
 - LR
 - Maximize log-likelihood
 - Minimizing training loss with regularization constraints
- Linear regression and support vector regression are also under the same umbrella
- Understanding the concept of training loss and regularization enables you to self-study many machine learning techniques

Quiz

- What are “support vectors” of SVM?
- When increasing training samples, will the size of “logistic regression model” increase?
- When increasing training samples, will the size of “linear SVM model” increase?
- When increasing training samples, will the size of “kernel SVM model” increase?

Appendix

Convex optimization and quadratic programming

- A convex optimization problem is one of the form

Minimize $f_0(\mathbf{x})$

Subject to $f_i(\mathbf{x}) \leq 0, i = 1, \dots, m$

$$\mathbf{a}_j^T \mathbf{x} = \mathbf{b}_j, j = 1, \dots, p$$

Where f_0, \dots, f_m are convex functions

- The convex optimization problem is called a quadratic programming (QP) if the objective function is (convex) quadratic, and the constraint functions are affine
 - Minimize $f_0(\mathbf{x}) = (1/2)\mathbf{x}^T \mathbf{P} \mathbf{x} + \mathbf{q}^T \mathbf{x} + \mathbf{r}$
 - Subject to $\mathbf{G} \mathbf{x} \preceq \mathbf{h}$ and $\mathbf{A} \mathbf{x} = \mathbf{b}$

Primal problem

- The standard form problem re-formulate as the **Primal problem**

$$\min_{\mathbf{x}} \max_{\lambda_i \geq 0, \mu} \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu})$$

- Why?

$$\begin{aligned} \max_{\lambda_i \geq 0, \mu} \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu}) &= \max_{\lambda_i \geq 0, \mu} \left[f(\mathbf{x}) + \sum_{i=1}^p \lambda_i g_i(\mathbf{x}) + \sum_{j=1}^m \mu_j h_j(\mathbf{x}) \right] \\ &= \max_{\lambda_i \geq 0, \mu} \left[f(\mathbf{x}) + \sum_{i=1}^p \lambda_i g_i(\mathbf{x}) \right] \left(\because h_j(\mathbf{x}) = 0 \right) \\ &= f(\mathbf{x}) \left(\because g_i(\mathbf{x}) \leq 0 \right) \end{aligned}$$

$$\Rightarrow \min_{\mathbf{x}} \max_{\lambda_i \geq 0, \mu} \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu}) = \min_{\mathbf{x}} f(\mathbf{x})$$

Dual problem

- Primal problem: $p^* = \min_{\mathbf{x}} \max_{\lambda_i \geq 0, \mu} \mathcal{L}(\mathbf{x}, \lambda, \mu)$
- Dual problem: $d^* = \max_{\lambda_i \geq 0, \mu} \min_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda, \mu)$
- $p^* \geq d^*$
 - The min of the max is no less than the max of the min
 - Duality gap: $p^* - d^*$

Strong duality

- $d^* = p^*$
- If the following conditions are true, then strong duality holds
 1. f and g_i 's are convex
 2. h_i 's are linear functions (i.e., Exists a_i and b_i such that $h_i(\mathbf{x}) = a_i^T \mathbf{x} + b_i$)
 3. Exists some \mathbf{x} such that $g_i(\mathbf{x}) \leq 0$
- In SVM, the above conditions holds
 - We may solve the dual problem instead of the primal problem

Lagrangian in SVM

$$\mathcal{L}(\mathbf{w}, b, \boldsymbol{\lambda}) = \frac{1}{2} \mathbf{w}^T \mathbf{w} + \sum \lambda_i \left[1 - y_i (\mathbf{w}^T \mathbf{x}_i + b) \right]$$

– No equality constraints (no μ 's)

$$\begin{cases} \nabla_{\mathbf{w}} \mathcal{L}(\mathbf{w}, b, \boldsymbol{\lambda}) = \mathbf{w} - \sum \lambda_i y_i \mathbf{x}_i := 0 \\ \nabla_b \mathcal{L}(\mathbf{w}, b, \boldsymbol{\lambda}) = - \sum \lambda_i y_i := 0 \end{cases}$$

$$\Rightarrow \begin{cases} \mathbf{w} = \sum \lambda_i y_i \mathbf{x}_i \\ \sum \lambda_i y_i := 0 \end{cases}$$

Primal and dual problem in SVM

- Primal:

$$p^* = \min_{\mathbf{w}} \max_{\lambda_i \geq 0} \mathcal{L}(\mathbf{w}, \lambda)$$

- Dual:

$$\begin{cases} \mathbf{w} = \sum \lambda_i y_i \mathbf{x}_i \\ \sum \lambda_i y_i := 0 \end{cases}$$

$$d^* = \max_{\lambda_i \geq 0} \min_{\mathbf{w}} \mathcal{L}(\mathbf{w}, \lambda) = \max_{\lambda_i \geq 0} \min_{\mathbf{w}} \frac{1}{2} \mathbf{w}^T \mathbf{w} + \sum \lambda_i [1 - y_i (\mathbf{w}^T \mathbf{x}_i + b)] = \max_{\lambda_i \geq 0} \min_{\mathbf{w}} \frac{1}{2} \sum_{i,j} \lambda_i \lambda_j y_i y_j \mathbf{x}_i^T \mathbf{x}_j + \sum [\lambda_i - \lambda_i y_i (\mathbf{w}^T \mathbf{x}_i + b)] = \max_{\lambda_i \geq 0} \left[-\frac{1}{2} \sum_{i,j} \lambda_i \lambda_j y_i y_j \langle \mathbf{x}_i, \mathbf{x}_j \rangle + \sum \lambda_i \right]$$

Subject to: $\lambda_i \geq 0$ and $\sum \lambda_i y_i = 0$

\therefore KKT condition

\therefore differentiate of the primal w.r.t. b

The dual problem

$$\max_{\lambda_i \geq 0} \left[-\frac{1}{2} \sum_{i,j} \lambda_i \lambda_j y_i y_j \langle \mathbf{x}_i \mathbf{x}_j \rangle + \sum \lambda_i \right]$$

Subject to $\lambda_i \geq 0$ and $\sum \lambda_i y_i = 0$

- λ_i 's are the only unknowns
- This is a quadratic programming (QP) problem
 - A global maximum of λ_i 's can always be found
 - How to solve? Use standard QP solvers
- We don't compute explicitly compute \mathbf{w}
- Discriminant function:

$$f(\mathbf{x}_t) = \mathbf{w}^T \mathbf{x}_t + b = \sum \lambda_i y_i \langle \mathbf{x}_i, \mathbf{x}_t \rangle + b$$

Optimization type of solving SVM

- Dual QP
 - SMO, SVM-light, etc.
 - Many available QP solvers
 - List: <http://www.numerical.rl.ac.uk/people/nimg/qp/qp.html>
- Primal SGD
 - NORMA
 - SVM-SGD
- Dual Coordinate Descent
 - LibLinear
